One of the most commonly repeated criticisms of wind power is that it kills birds. The giant spinning turbines are basically bird death traps—and often they cut through prime flying space, making the carnage even worse. At least that's the story. But how many birds really do die?

- [Myth Debunked: Wind Farms Don't Alter the Climate](#)

If you look around for statistics about bird deaths from wind turbines get you wildly different numbers. Some **say just 10,000 birds a year** meet their end at the hands (blades) of the wind industry. Others **ramp that number up to 600,000**. Now, a new study tried to actually use science to estimate. Of course, they didn't go to each turbine and count how many little feathered bodies they found at the base. Instead, they combed the literature for all the studies they could find on bird deaths, and tried to combine them into an estimate. This meant searching for fun things like **"'bird AND wind turbine' with 'collision,' 'mortality,' 'fatality,' 'carcass,' and 'post-construction.'"** And then—even more cheerful—searching all those terms again, but "with 'bird' replaced by 'avian' and 'wildlife'; and 'turbine' replaced by 'farm,' 'facility' and 'energy.'"

In the end, using 58 mortality estimates that met their criteria, they came up with an estimate.

According to the current literature somewhere between 140,000 and 328,000 birds die each year from collisions with wind turbines.

That's not all, [explains the blog Natural Reactions](#):

In addition, it appears that there is a greater risk of fatal collisions with taller turbines. This is a real problem, as larger wind turbines may provide [more efficient](#) energy generation. Consequently, it is expected that **new wind farms will contain even bigger turbines, which will result in even more bird deaths. Future developments** therefore will have to give very careful consideration to potential wildlife impacts when planning the type of turbine to install.

The estimate, and conclusions, don't let wind turbines off the hook. **And with recent rulings to try and protect certain species** from the spinning blades, the scrutiny will probably continue when it comes to bird deaths due to wind power.

But at least now there's a scientifically derived number for those deaths. More from Smithsonian.com :

16- <https://wcfm.org/2014/03/31/windfarms-vertebrates-and-reproduction/>

400 goats died in Taiwan in 2009. These animals, kept on a windfarm, were unable to sleep:

“the goats looked skinny and they weren’t eating. One night I went out to the farmhouse and the goats were all standing up; they weren’t sleeping” (2).

In Denmark, which is the EU’s leader in mink farming, millions of Danish kroner were lost in damaged pelts when wind turbines started to operate near a mink farm. The animals became aggressive, attacking one another, and resulting in many deaths.

In Poland, a recent peer-reviewed study on domestic geese concluded that: *“the results indicate the negative impact of the immediate vicinity of wind turbines on feed consumption, weight gain and cortisol concentration in blood” (4).*

Biologist Dr. Lynne Knuth, in a letter to the Public Service Commission of Wisconsin, testified as follows: *“The problems with animal reproduction reported in the wind farms in Wisconsin are lack of egg production, problems calving, spontaneous abortion (embryonic mortality), stillbirth, miscarriage and teratogenic effects:*

Nova Scotia, Canada: the Ocean Breeze Emu Farm, popular among tourists, has closed down. The vibrations from nearby wind turbines, 850 meters away, have killed many of the emus, the owners announced. *“Our birds became very aggressive. They were never like that. They were very docile”*, Debi VanTassell said. **The big birds were not sleeping.**

- **In chickens:** *Crossed beaks, missing eyeballs, deformities of the skull (sunken eyes), joints of feet/legs bent at odd angles (Jim Vollmer, personal communication)*

- **In cattle:** *missing eyes and tails (updated Excerpts from the Final Report of the Township of Lincoln Wind Turbine Moratorium Committee).*

“It is disturbing to me that in chickens and cows in separate wind farms (separated by 50 miles) similar teratogenic effects are being observed, namely missing eyeballs. Based on the correlation of effects seen experimentally and those seen in the wind farm in chickens, these defects may be due to low frequency vibration. Jim Vollmer, the farmer who owns these chickens, reports that the tin structures on his farm buildings vibrate. If the infrasound/ low-frequency sound is strong enough to vibrate structures on his farm as it passes through, what is it doing to the delicate connections and circulation inside the developing chicken embryos, and inside people, as it passes through them?”
